Spinal emergencies

Back pain is a common symptom often associated with transient or chronic non-emergent disorders. However, without urgent intervention spinal emergencies can occur resulting in permanent sensory and motor deficits, loss of sphincter control and sexual function.[1] A sound understanding of the various emergent spinal conditions is important and maintaining a high level of suspicion is essential when assessing and managing patients presenting with back pain.

This CPG deals with non-traumatic causes of spinal emergencies; for trauma related spinal injuries please refer to CPG: Spinal cord injury.

Cauda equina and conus medullaris syndromes: Caused by lumbar or thoracic disc protrusion or extrusion, trauma, tumours, infections, spinal stenosis or epidural haematoma. Management requires surgical decompression and if undertaken > 48 hrs after presentation it is rarely successful. Cauda equina syndrome presentations vary and can occur acutely over several hours, as a subacute onset in a patient with long history of chronic back pain or slowly and insidiously progressing to sphincter dysfunction.[2-3]

Epidural abscess: Infection of the epidural space that can lead to damage of the spinal cord by direct infection, compression or vascular compromise. Definitive treatment includes surgical decompression and antibiotic therapy.[1-3]

Vertebral osteomyelitis or discitis: Infection of the bones of the spine or inflammation of the vertebral disc space respectively that can lead to significant neurological compromise if misdiagnosed or left untreated.[1-3]

Tumours: Benign or malignant tumours of the spine can present with back pain with or without neurological symptoms, resulting from compression of the spinal cord or cauda equina.[1,2]

Clinical features

Concerning clinical signs and risk factors [1-4]

- Diaphoresis, hunger, tingling
- Body temperature < 36°C or > 38°C
- Age < 20 years or > 50 years
- Recent onset of pain without trauma or lifting
- Severe pain at rest or progressively worsening pain
- Bilateral sciatic nerve pain
- Obvious structural deformity
- Urinary retention AND/OR incontinence
- Bowel incontinence
- Lower extremity neurological deficit
- History of cancer
- Fever, chills, night sweats or recent weight loss
- Recent infection or immunosuppression
- Perineal, perianal or saddle sensory loss
- IV drug use or recent steroid therapy
**Risk Assessment**

- New onset, pre-existing or chronic back pain patients can all develop spinal emergencies, therefore a current diagnosis regarding back pain does not rule out a spinal emergency.\(^1\)

**Additional information**

- The assessment of back pain is complex and requires multi-modal investigation. **ALL patients with back pain should be transported for further medical assessment.**
- When assessing the patient with back pain, it is important to gather a full medical history including progression of symptoms and any changes in symptom presentation from pre-existing or chronic conditions.

**Consider:**

- IV access
- Antiemetic
- Analgesia

**Transport to hospital**

Pre-notify as appropriate

---

**Note:** Officers are only to perform procedures for which they have received specific training and authorisation by the QAS.
