Skin closure – Simple interrupted suturing

Simple interrupted suturing using non-absorbable material is a common method of closing skin defects following injury. The aim of suturing is to promote rapid healing without complications.

Any wound not suitable for this technique should be reviewed by the patient’s primary health care provider or at a health care facility.

**Indications**

- Uncontaminated simple lacerations with the following criteria:
  - Adult patient ≥ 16;
  - ≤ 4 hours from injury AND
  - easily apposed wound edges with non ragged edges.

**Contraindications**

- Wounds unable to be easily approximated
- Wounds caused by animal/human bites or marine injury (e.g. coral cuts)
- Wounds with evidence of infection
- Wounds over joints, the face (including chin), scalp, hands, ears, armpit, genitals or feet
- Obvious tissue defect or cavity (dead space) under the wound
- History of keloid scarring
- Potential damage to underlying structures (i.e. tendons or bone on view)
- Skin flaps or tear

**Complications**

- Wound dehiscence
- Infection
- Cosmetic (e.g. scarring)
1. Inspect the wound and confirm suitability for simple interrupted suturing.

2. Thoroughly clean the wound using sodium chloride 0.9%.

3. Prepare a suitable volume of lidocaine 1% (lignocaine 1%) – refer to DTP: Lidocaine 1% (lignocaine 1%).

4. Infiltrate the skin surrounding the wound – refer to CPP: Drug & fluid administration / Direct infiltration of local anaesthetic.

5. Explore the wound to ensure that the bottom can be clearly visualised and no underlying structures are potentially damaged.
6. Thoroughly re-clean the wound using sodium chloride 0.9%.

7. Remove excess moisture with a sterile gauze / combine.

8. Prepare a sterile field by draping the wound with a sterile fenestrated drape.

9. Select an appropriate suture diameter for the location and type of wound – use the thinnest possible suture material that will provide adequate strength to close the wound.

10. Open the suture pack and place contents on a prepared sterile field.

11. Perform appropriate hand hygiene and don sterile gloves – refer to CPP: Other / Donning and doffing of medical gloves.

12. Grip the needle with the needle holder ready for suturing.
13. Consider gently stretching the suture material to remove its ‘memory’.

14. Lift the tissue edge and insert the first suture in the middle of the wound – ensure the wound edges are slightly everted.

- **a)** With the needle tip perpendicular to the skin penetrate the epidermis on one side and gently rotate the wrist to advance the needle through the subcutaneous tissue.

- **b)** Penetrate the subcutaneous tissue on the wound’s other side and exit via the epidermis above.

- **c)** Gently pull the suture material through the skin leaving approximately 10–20 mm exposed from the entry site.
Procedure – Skin closure – Simple interrupted suturing

d) Wrap the suture material twice around the needle holder in a clockwise direction.

e) Grab the short end of the suture material with the needle holder.

f) Gently pull through the suture material loops ensuring the knot lies flat and slightly off centre (3–4 mm from the wound edge). The short end of the suture material should now be on the opposite side.

g) Finalise the securing suture by repeating the preceding steps (d–f) twice with a single throw for each knot to end with (h).

h) Finalised knot.
Procedure – Skin closure – Simple interrupted suturing

i) Cut the tail ends of the suture material to leave 1–2 cm of suture material.

15. Commencing at the wound edge furthest from the paramedic, repeat steps 14 (a–i) until the wound is fully apposed.

16. Ensure the skin between sutures is not pucked or pulled too tight as this may cause tissue ischaemia and/or a poor cosmetic result.

17. Re-clean the closed wound with sodium chloride 0.9%.
18. Remove excess moisture with a sterile gauze/combine.
19. Once dry, apply an appropriate non-adherent dressing to the wound.
20. Provide the patient with the following wound care instructions:
   a) Avoid contact with water – if the wound becomes wet and/or dirty it may be gently cleaned with water and have a new dressing applied.
   b) Arrange Medical Officer review (including Tetanus vaccination consideration) within 24 hours.
   c) A small amount of swelling, pain or redness that goes away within a few days is common during wound healing. If these symptoms worsen or persist, please contact your doctor.

Additional information

Guide for appropriate suture diameter and suggested time to removal of sutures.

**Additional information (cont.)**

- Antibiotics are not routinely indicated for simple lacerations.
- Wounds have only 7% of their final strength on day five.[9]
- Sutures (non-facial) knots should be positioned approximately 3–4 mm from the skin edges and 5–10 mm apart.

**Audit**

- All wounds involving paramedic initiated suturing and Histoacryl® skin adhesive application are subject to clinical audit and review. Officers are required to obtain informed consent from the patient and send the following information to QASLARU.Review@ambulance.qld.gov.au:
  - Case Number
  - Paramedic name and medal number; AND
  - Photographs (before and after closure).

- The collection of clinical image for the purpose of clinical consultation AND/OR quality assurance forms part of the patient’s health care record and their existence must be documented on the patient’s eARF. This can be done by selecting the image tick box in the eARF app at the following location: Care / Procedure / Consult / Clinical Consultation and Advice Line.
